

Chapter 24

Gauss's Law

Gauss' Law

Gauss' Law can be used as an alternative procedure for calculating electric fields.

Gauss' Law is based on the inverse-square behavior of the electric force between point charges.

It is convenient for calculating the electric field of highly symmetric charge distributions.

Gauss' Law is important in understanding and verifying the properties of conductors in electrostatic equilibrium.

Electric Flux

Electric flux is the product of the magnitude of the electric field and the surface area, A , perpendicular to the field.

$$\Phi_E = EA$$

Units: $\text{N} \cdot \text{m}^2 / \text{C}$

Electric Flux, General Area

The electric flux is proportional to the number of electric field lines penetrating some surface.

The field lines may make some angle θ with the perpendicular to the surface.

Then $\Phi_E = EA \cos \theta$

Electric Flux, Interpreting the Equation

The flux is a maximum when the surface is perpendicular to the field.

- $\theta = 0^\circ$

The flux is zero when the surface is parallel to the field.

- $\theta = 90^\circ$

If the field varies over the surface, $\Phi = EA \cos \theta$ is valid for only a small element of the area.

Electric Flux, General

In the more general case, look at a small area element.

$$\Delta\Phi_E = E_i \Delta A_i \cos\theta_i = \vec{E}_i \cdot \Delta\vec{A}_i$$

In general, this becomes

$$\Phi_E = \lim_{\Delta A_i \rightarrow 0} \sum E_i \cdot \Delta A_i$$

$$\Phi_E = \int_{\text{surface}} \vec{E} \cdot d\vec{A}$$

- The surface integral means the integral must be evaluated over the surface in question.

In general, the value of the flux will depend both on the field pattern and on the surface.

The electric field makes an angle θ_i with the vector $\Delta\vec{A}_i$, defined as being normal to the surface element.

Electric Flux, Closed Surface

Assume a closed surface

The vectors $\Delta\vec{A}_i$ point in different directions.

- At each point, they are perpendicular to the surface.
- By convention, they point outward.

Flux Through Closed Surface, cont.

At (1), the field lines are crossing the surface from the inside to the outside; $\theta < 90^\circ$, Φ is positive.

At (2), the field lines graze surface; $\theta = 90^\circ$, $\Phi = 0$

At (3), the field lines are crossing the surface from the outside to the inside; $180^\circ > \theta > 90^\circ$, Φ is negative.

Flux Through Closed Surface, final

The **net** flux through the surface is proportional to the net number of lines leaving the surface.

- This net number of lines is the number of lines leaving the surface minus the number entering the surface.

If E_n is the component of the field perpendicular to the surface, then

$$\Phi_E = \oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \oint E_n dA$$

- The integral is over a closed surface.

Flux Through a Cube, Example

The field lines pass through two surfaces perpendicularly and are parallel to the other four surfaces.

For face 1, $E = -E\ell^2$

For face 2, $E = E\ell^2$

For the other sides, $E = 0$

Therefore, $E_{total} = 0$

Karl Friedrich Gauss

1777 – 1855

Made contributions in

- Electromagnetism
- Number theory
- Statistics
- Non-Euclidean geometry
- Cometary orbital mechanics
- A founder of the German Magnetic Union
 - Studies the Earth's magnetic field

Gauss's Law, Introduction

Gauss's law is an expression of the general relationship between the net electric flux through a closed surface and the charge enclosed by the surface.

- The closed surface is often called a *gaussian surface*.

Gauss's law is of fundamental importance in the study of electric fields.

Gauss's Law – General

A positive point charge, q , is located at the center of a sphere of radius r .

The magnitude of the electric field everywhere on the surface of the sphere is

$$E = k_e q / r^2$$

Gauss's Law – General, cont.

The field lines are directed radially outward and are perpendicular to the surface at every point.

$$\Phi_E = \oiint \vec{E} \cdot d\vec{A} = E \oiint dA$$

This will be the net flux through the gaussian surface, the sphere of radius r .

We know $E = k_e q / r^2$ and $A_{\text{sphere}} = 4\pi r^2$,

$$\Phi_E = 4\pi k_e q = \frac{q}{\epsilon_o}$$

Gauss's Law – General, notes

The net flux through any closed surface surrounding a point charge, q , is given by q/ϵ_0 and is independent of the shape of that surface.

The net electric flux through a closed surface that surrounds no charge is zero.

Since the electric field due to many charges is the vector sum of the electric fields produced by the individual charges, the flux through any closed surface can be expressed as

$$\oint \vec{E} \cdot d\vec{A} = \oint (\vec{E}_1 + \vec{E}_2 \dots) \cdot d\vec{A}$$

Gaussian Surface, Example

Closed surfaces of various shapes can surround the charge.

- Only S_1 is spherical

Verifies the net flux through any closed surface surrounding a point charge q is given by q/ϵ_0 and is independent of the shape of the surface.

Gaussian Surface, Example 2

The charge is *outside* the closed surface with an arbitrary shape.

Any field line entering the surface leaves at another point.

Verifies the electric flux through a closed surface that surrounds no charge is zero.

Gauss's Law – Final

The mathematical form of Gauss's law states

$$\Phi_E = \oint \vec{E} \cdot d\vec{A} = \frac{q_{\text{in}}}{\epsilon_0}$$

- q_{in} is the net charge inside the surface.

\vec{E} represents the electric field at any point on the surface.

- \vec{E} is the *total electric field* and may have contributions from charges both inside and outside of the surface.

Although Gauss's law can, in theory, be solved to find \vec{E} for any charge configuration, in practice it is limited to symmetric situations.

Applying Gauss's Law

To use Gauss's law, you want to choose a gaussian surface over which the surface integral can be simplified and the electric field determined.

Take advantage of symmetry.

Remember, the gaussian surface is a surface you choose, it does not have to coincide with a real surface.

Conditions for a Gaussian Surface

Try to choose a surface that satisfies one or more of these conditions:

- The value of the electric field can be argued from symmetry to be constant over the surface.
- The dot product of $\vec{E} \cdot d\vec{A}$ can be expressed as a simple algebraic product EdA because \vec{E} and $d\vec{A}$ are parallel.
- The dot product is 0 because \vec{E} and $d\vec{A}$ are perpendicular.
- The field is zero over the portion of the surface.

If the charge distribution does not have sufficient symmetry such that a gaussian surface that satisfies these conditions can be found, Gauss' law is not useful for determining the electric field for that charge distribution.

Field Due to a Spherically Symmetric Charge Distribution

Select a sphere as the gaussian surface.

For $r > a$

$$\Phi_E = \oint \vec{E} \cdot d\vec{A} = \oint E dA = \frac{q_{\text{in}}}{\epsilon_0}$$

$$E = \frac{Q}{4\pi\epsilon_0 r^2} = k_e \frac{Q}{r^2}$$

For points outside the sphere, a large, spherical gaussian surface is drawn concentric with the sphere.

a

Spherically Symmetric, cont.

Select a sphere as the gaussian surface, $r < a$.

$$q_{\text{in}} < Q$$

$$q_{\text{in}} = r (4/3\pi r^3)$$

$$\Phi_E = \oint \vec{E} \cdot d\vec{A} = \oint E dA = \frac{q_{\text{in}}}{\epsilon_o}$$

$$E = \frac{q_{\text{in}}}{4\pi\epsilon_o r^2} = k_e \frac{Q}{a^3} r$$

For points inside the sphere, a spherical gaussian surface smaller than the sphere is drawn.

b

Spherically Symmetric Distribution, final

Inside the sphere, E varies linearly with r

- $E \rightarrow 0$ as $r \rightarrow 0$

The field outside the sphere is equivalent to that of a point charge located at the center of the sphere.

Field at a Distance from a Line of Charge

Select a cylindrical charge distribution .

- The cylinder has a radius of r and a length of ℓ .

\vec{E} is constant in magnitude and perpendicular to the surface at every point on the curved part of the surface.

Use Gauss's law to find the field.

$$\Phi_E = \oint \vec{E} \cdot d\vec{A} = \oint E dA = \frac{q_{\text{in}}}{\epsilon_0}$$

$$E(2\pi r \ell) = \frac{\lambda \ell}{\epsilon_0}$$

$$E = \frac{\lambda}{2\pi\epsilon_0 r} = 2k_e \frac{\lambda}{r}$$

Field Due to a Line of Charge, cont.

The end view confirms the field is perpendicular to the curved surface.

The field through the ends of the cylinder is 0 since the field is parallel to these surfaces.

Field Due to a Plane of Charge

\vec{E} must be perpendicular to the plane and must have the same magnitude at all points equidistant from the plane.

Choose a small cylinder whose axis is perpendicular to the plane for the gaussian surface.

\vec{E} is parallel to the curved surface and there is no contribution to the surface area from this curved part of the cylinder.

The flux through each end of the cylinder is EA and so the total flux is $2EA$.

Field Due to a Plane of Charge, final

The total charge in the surface is σA .

Applying Gauss's law:

$$\Phi_E = 2EA = \frac{\sigma A}{\epsilon_0} \text{ and } E = \frac{\sigma}{2\epsilon_0}$$

Note, this does not depend on r .

Therefore, the field is uniform everywhere.

Properties of a Conductor in Electrostatic Equilibrium

When there is no net motion of charge within a conductor, the conductor is said to be in **electrostatic equilibrium**.

The electric field is zero everywhere inside the conductor.

- Whether the conductor is solid or hollow

If the conductor is isolated and carries a charge, the charge resides on its surface.

The electric field at a point just outside a charged conductor is perpendicular to the surface and has a magnitude of σ/ϵ_0 .

- σ is the surface charge density at that point.

On an irregularly shaped conductor, the surface charge density is greatest at locations where the radius of curvature is the smallest.

Property 1: $\text{Field}_{\text{inside}} = 0$

Consider a conducting slab in an external field.

If the field inside the conductor were not zero, free electrons in the conductor would experience an electrical force.

These electrons would accelerate.

These electrons would not be in equilibrium.

Therefore, there cannot be a field inside the conductor.

Property 1: $\text{Field}_{\text{inside}} = 0$, cont.

Before the external field is applied, free electrons are distributed throughout the conductor.

When the external field is applied, the electrons redistribute until the magnitude of the internal field equals the magnitude of the external field.

There is a net field of zero inside the conductor.

This redistribution takes about 10^{-16} s and can be considered instantaneous.

If the conductor is hollow, the electric field inside the conductor is also zero.

- Either the points in the conductor or in the cavity within the conductor can be considered.

Property 2: Charge Resides on the Surface

Choose a gaussian surface inside but close to the actual surface.

The electric field inside is zero (property 1).

There is no net flux through the gaussian surface.

Because the gaussian surface can be as close to the actual surface as desired, there can be no charge inside the surface.

Property 2: Charge Resides on the Surface, cont.

Since no net charge can be inside the surface, any net charge must reside ***on*** the surface.

Gauss's law does not indicate the distribution of these charges, only that it must be on the surface of the conductor.

Property 3: Field's Magnitude and Direction

Choose a cylinder as the gaussian surface.

The field must be perpendicular to the surface.

- If there were a parallel component to \vec{E} , charges would experience a force and accelerate along the surface and it would not be in equilibrium.

Property 3: Field's Magnitude and Direction, cont.

The net flux through the gaussian surface is through only the flat face outside the conductor.

- The field here is perpendicular to the surface.

Applying Gauss's law

$$\Phi_E = EA = \frac{\sigma A}{\epsilon_0} \text{ and } E = \frac{\sigma}{\epsilon_0}$$

Sphere and Shell Example

Conceptualize

- Similar to the sphere example
- Now a charged sphere is surrounded by a shell
- Note charges

Categorize

- System has spherical symmetry
- Gauss' Law can be applied

Sphere and Shell Example, cont.

Analyze

- Construct a Gaussian sphere between the surface of the solid sphere and the inner surface of the shell.
 - Region 2
 - $a < r < b$
 - Charge inside the surface is $+Q$
- The electric field lines must be directed radially outward and be constant in magnitude on the Gaussian surface.

Sphere and Shell Example, 3

Analyze, cont.

- The electric field for each area can be calculated.

$$E_1 = k_e \frac{Q}{a^3} r \quad (\text{for } r < a)$$

$$E_2 = k_e \frac{Q}{r^2} \quad (\text{for } a < r < b)$$

$$E_3 = 0 \quad (\text{for } b < r < c)$$

$$E_4 = -k_e \frac{Q}{r^2} \quad (\text{for } r > c)$$

Sphere and Shell Example

Finalize

- Check the net charge.
- Think about other possible combinations.
 - What if the sphere were conducting instead of insulating?
